Use whole-number heights, including 0. Follow each arrow: the gap between its two old heights becomes the new height at its tail. Make every new tower before changing any old tower.

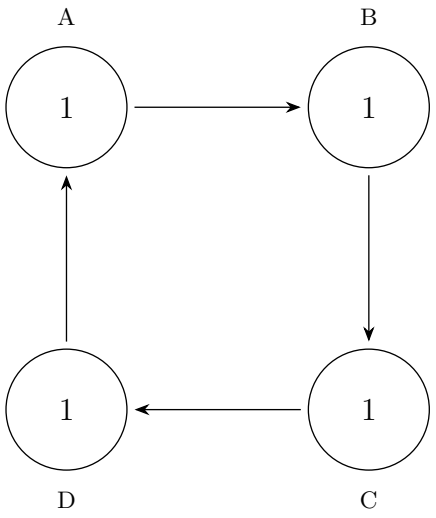

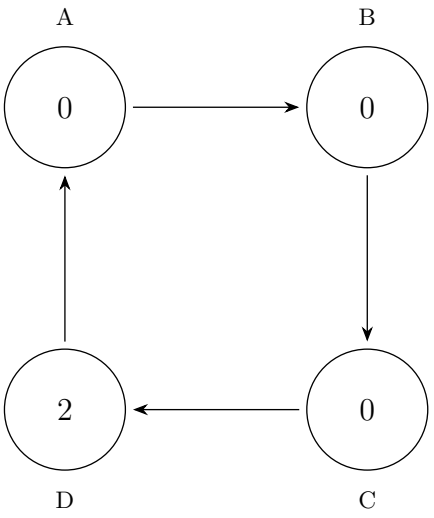

Edge A to B has gap 3, so new A is 3. All four gaps use the old ring.

Problem 3: Could each ring be the result of one move? Find an old ring that makes it, or explain why no old ring can work.

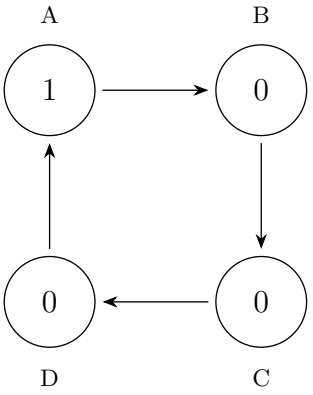

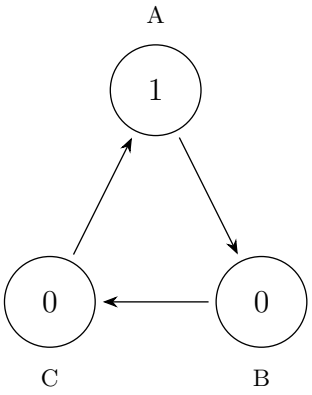

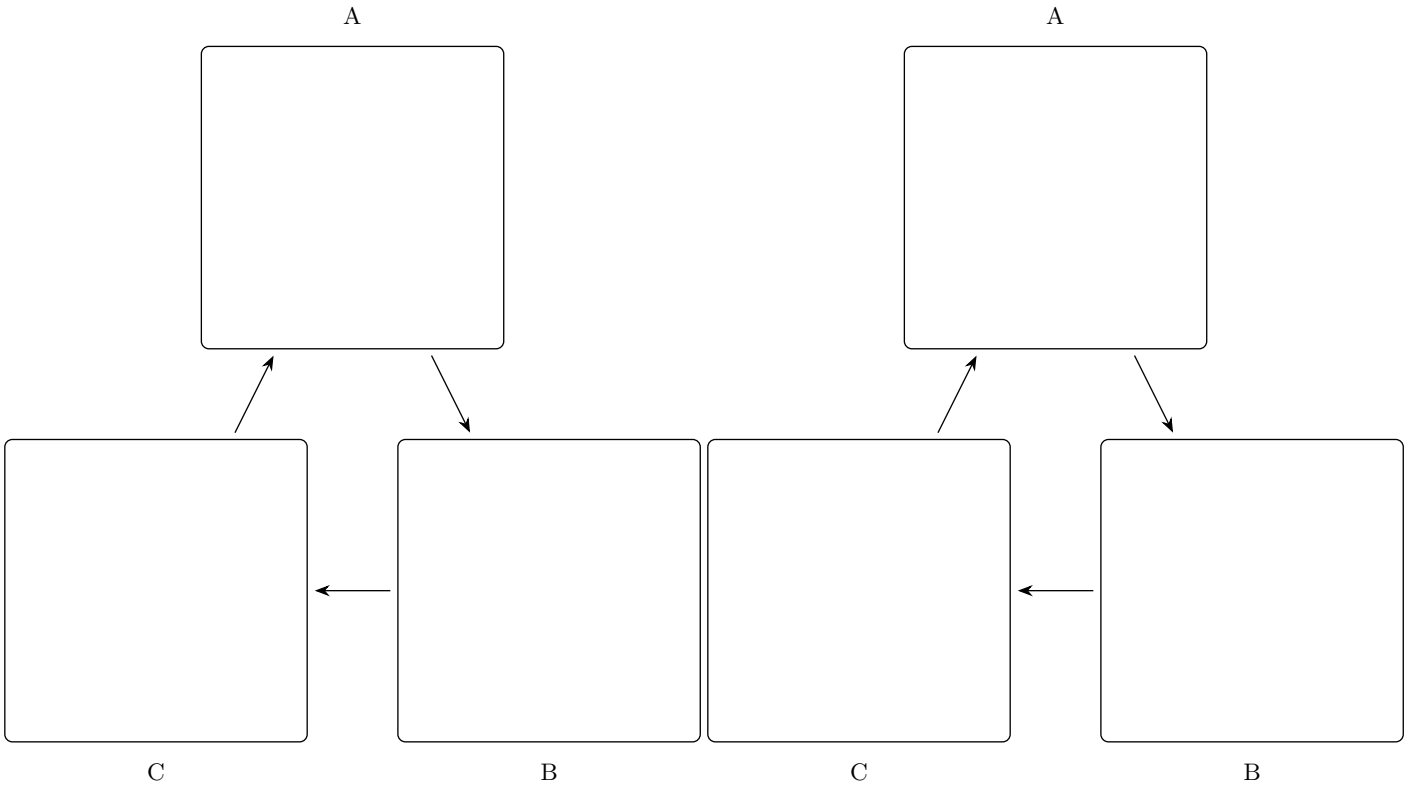

Problem 4: Use the gap rule on both rings. Keep going until the whole ring repeats or becomes all zeros. Does the number of stations change what can happen?

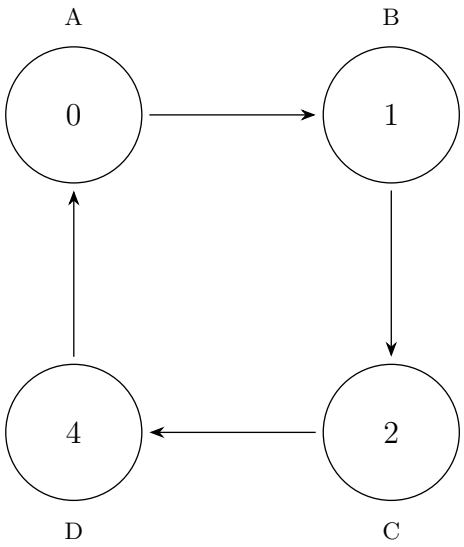

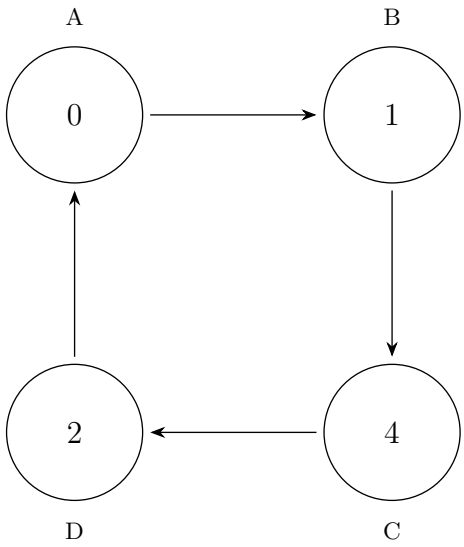

old

new

Problem 5: Try different orders of 0, 1, 2, and 4. Which order lasts longest? Two rings count as different here only when their A, B, C, D heights differ.

Problem 6: Can a new tower be taller than every old tower? Can the tallest height stay the same for a move? Give an explanation or an example for each claim.
