Put a counter on every bridge of a town before you walk it. A walk starts on an island and crosses bridges one after another. Each time it crosses a bridge, pick up that bridge's counter. A bridge with no counter cannot be crossed. Two islands can be joined by more than one bridge. In every town you can get from any island to any other.

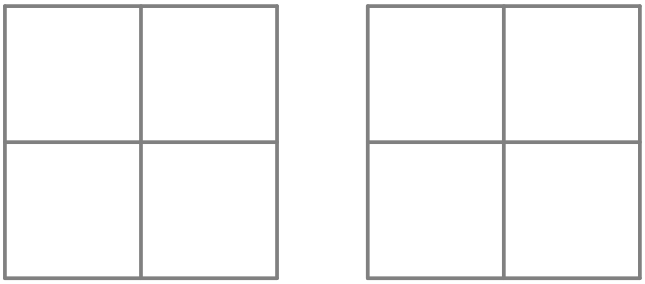

Problem 5: In each town, draw as few new bridges as you can so that a walk can pick up every counter and end on the island where it started.

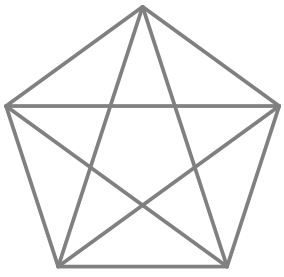

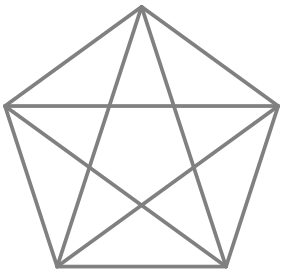

Problem 6: How can you tell, without walking, whether a town has a walk that picks up every counter, and where such a walk can start and end?

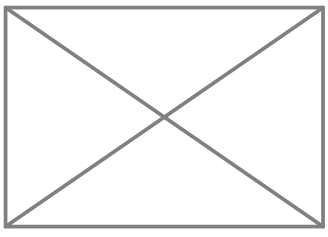

Problem 7: Trace each picture with a colored pencil, without lifting the pencil and without going over a line twice. If a picture cannot be traced this way, explain how you know.

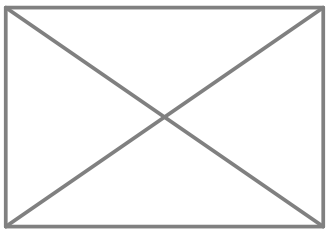

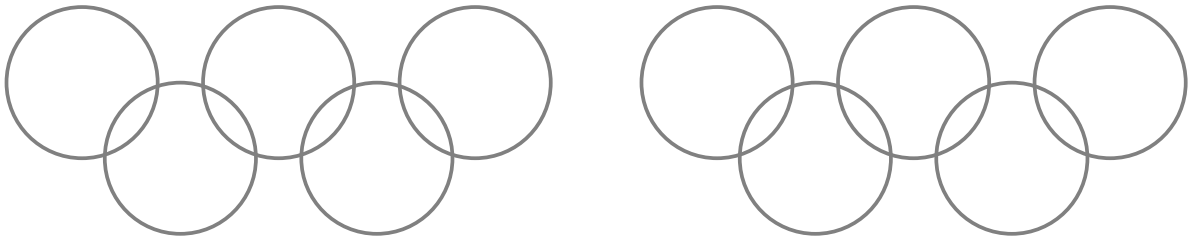

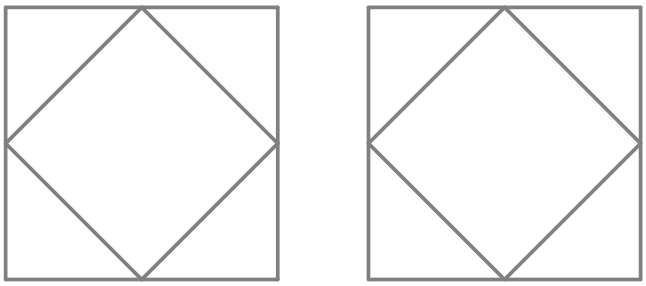

Problem 7, continued

Problem 8: Build each of these towns with hexagons and craft sticks for your partner to walk. Draw each town you build.

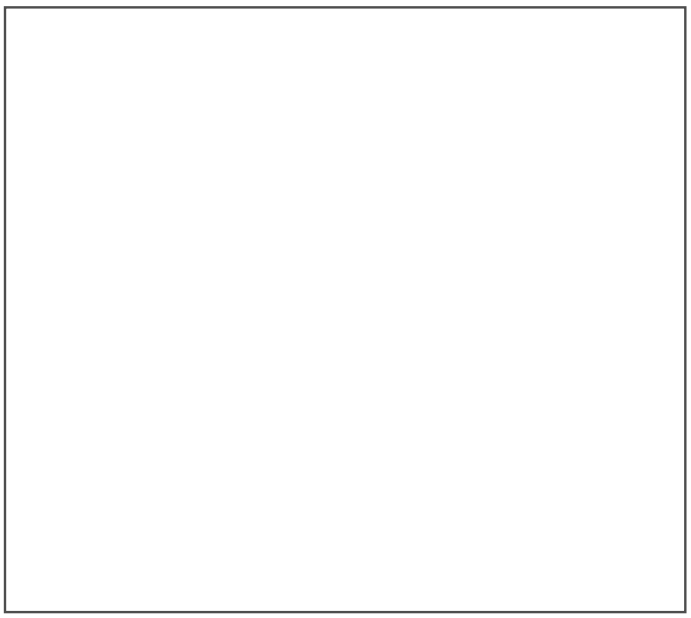

4 islands and 6 bridges. A walk that picks up every counter can start on any island.

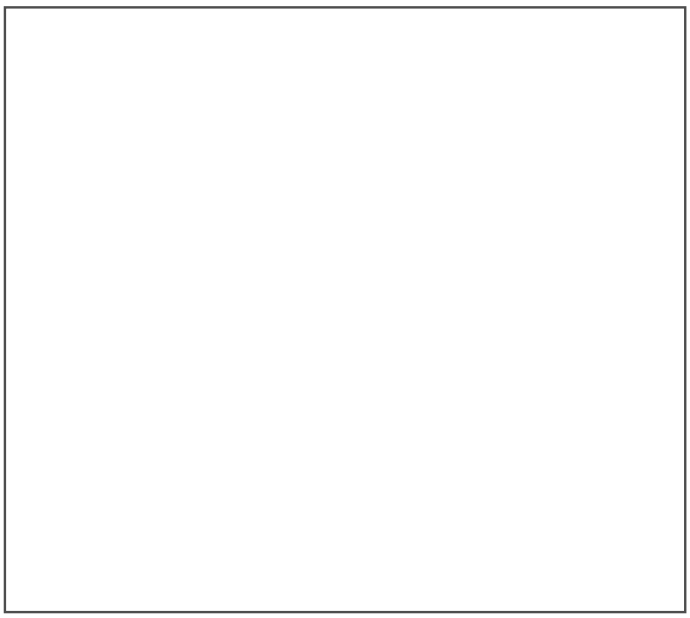

5 islands and 5 bridges. No walk picks up every counter.

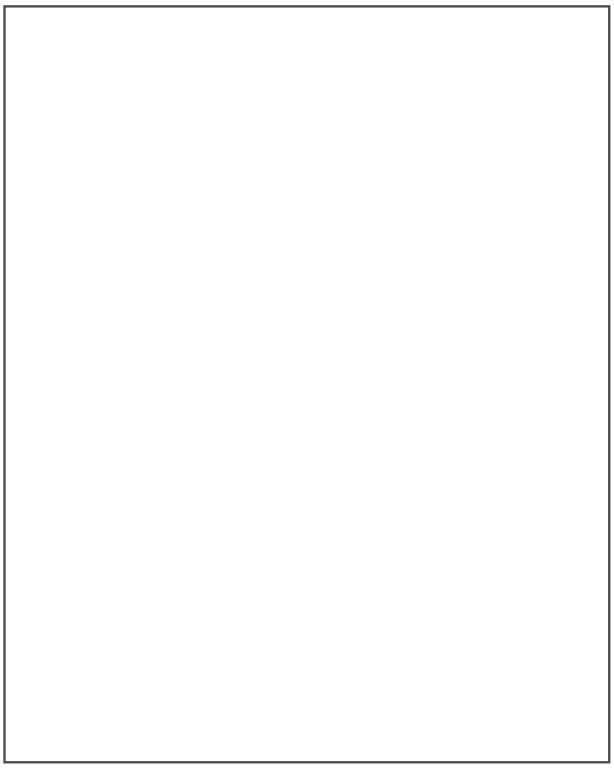

6 islands and 8 bridges. A walk that picks up every counter can start only on A or on F.

3 islands and 5 bridges. A walk that picks up every counter can start only on A or on B.

Problem 9: Can you make a town with at least one bridge where a walk that picks up every counter can start on only one island? Make one, or explain why it cannot be done.

Problem 10: A bridge can hold two counters, and then a walk can cross it two times. In each town, put a second counter on as few bridges as you can so that a walk can pick up every counter and end on the island where it started. Color each bridge that gets a second counter.
