Use closed models with all their faces attached. A vertex is a corner of the assembled solid; an edge is shared by two faces. Count each assembled edge and vertex once. Tabs and glue overlaps do not count.

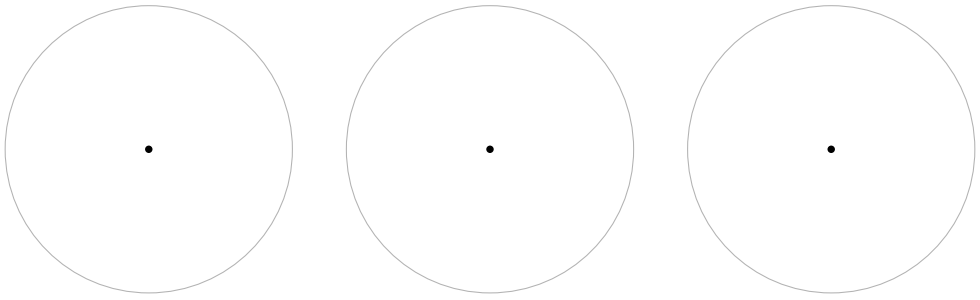

Problem 1: Find the vertices, edges and faces of each closed model.

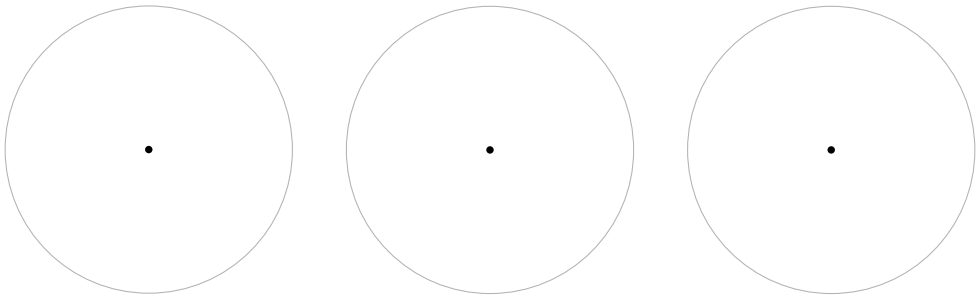

Model	Vertices V	Edges E	Faces F
 cube			
 tetrahedron			
 triangular prism			
 octahedron			

Join face corners around one point. Keep their sides meeting edge to edge and their marked vertices together. The gap is the missing part of a full turn when the corners lie flat.

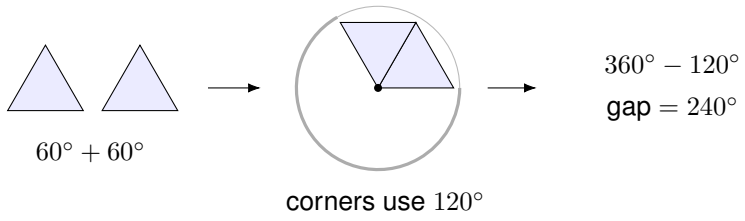

Problem 3: Which groups can close into a pointed corner with no inward dents? Which close flat with no gap? Make each group, then draw its gap with the corners laid flat.

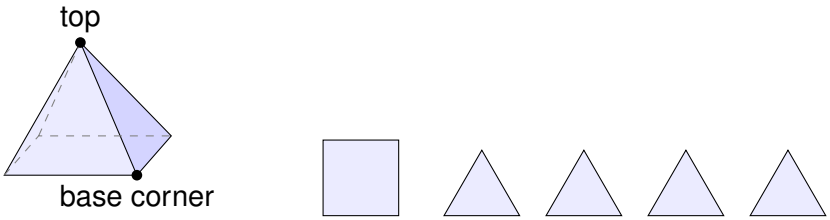

A full turn is $360°$. An equilateral triangle corner is $60°$; a square corner is $90°$. A vertex's gap is $360°$ minus its face-corner angles.

Problem 4: Find the gap at every vertex of each closed model. How many full turns do all its gaps make together?

Model	Vertices	Face corners at one vertex	Gap at one vertex	All gaps together
Cube				
Tetrahedron				
Triangular prism				
Octahedron				

Problem 5: The square pyramid has one square face and four equilateral triangle faces. Which corner leaves the bigger gap, the top or a base corner? Find its total gap.

Vertex type	How many?	Face corners meeting there	Gap at each one
Top			
Base corner
