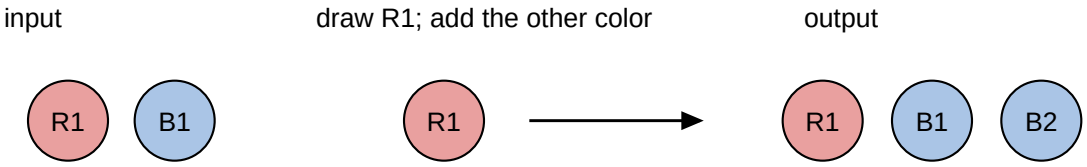
Start with R1 and B1. A random draw gives every counter the same chance. Always return the draw and mix. The first added counter gets mark 2; the next gets mark 3.



Problem 1: Compare three rules: add the drawn color, add the other color, or add nothing. Start R1, B1 for each story. Which rule most often gives one red and one blue draw in two draws? Settle it using all the marked stories.

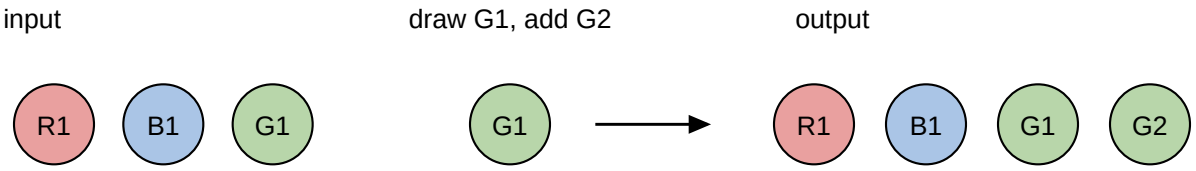
add drawn color	add other color	add nothing

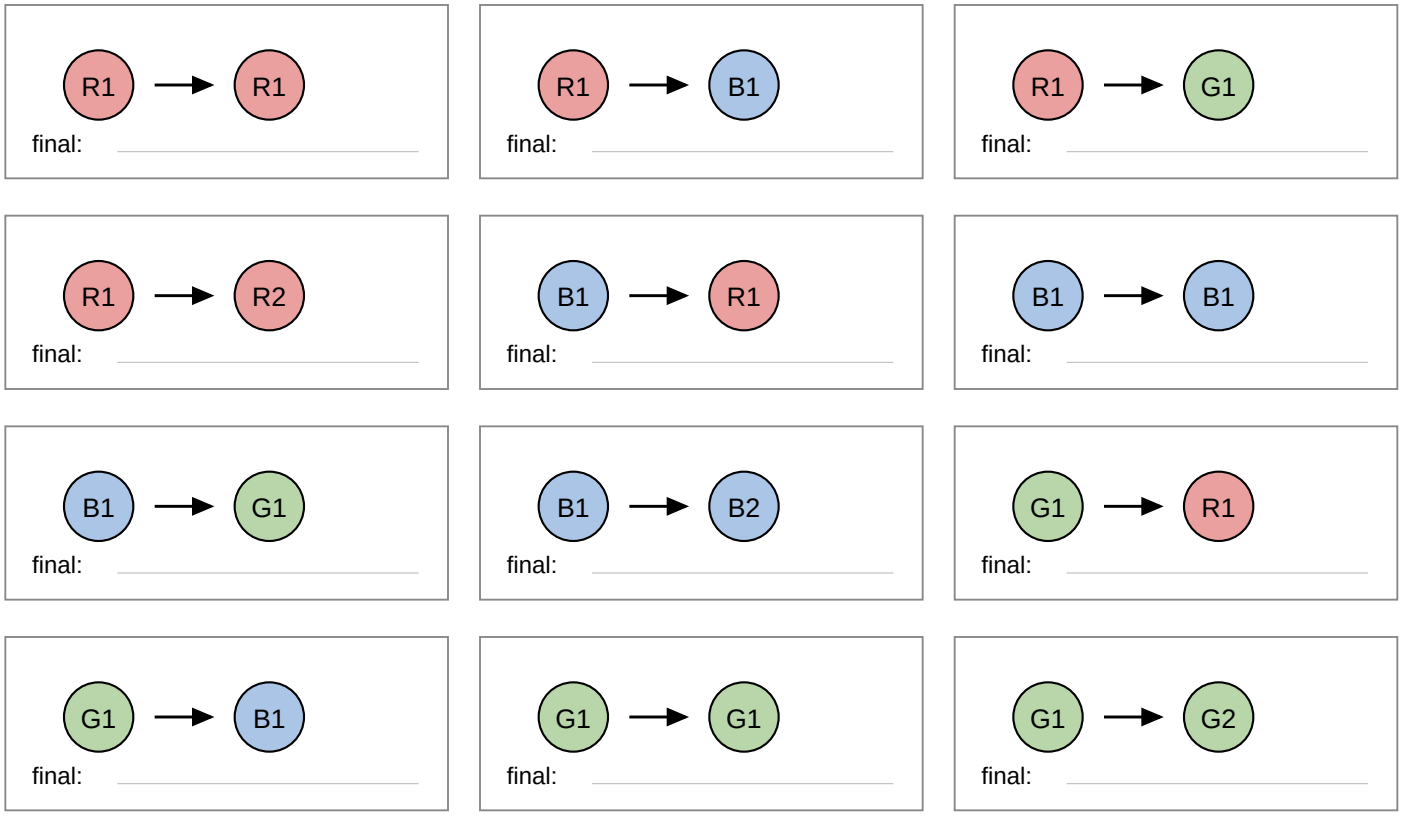
Use the copying rule: start R1, B1; return each draw, add its own color, and mix. Choose a possible story yourself when designing a bag. For the next random draw, every counter now in the bag has the same chance.

Problem 2: After four copying draws, make the next red draw as likely as possible, as unlikely as possible, and exactly as likely as blue. Give a story and a forecast for each. Can different stories give the same forecast?

red most likely story: _____	next red forecast _____
red least likely story: _____	next red forecast _____
red and blue tied story: _____	next red forecast _____

Start R1, B1, G1. Return each draw, add one of its own color, and mix. The first added copy gets mark 2; the next gets mark 3. Original counters stay in the bag.





Problem 3: Use these equally likely marked two-draw stories to find every final color-count bag. Do all bags have the same chance, even though color words may not? Predict the color-count bags after three draws and test your prediction exactly.
