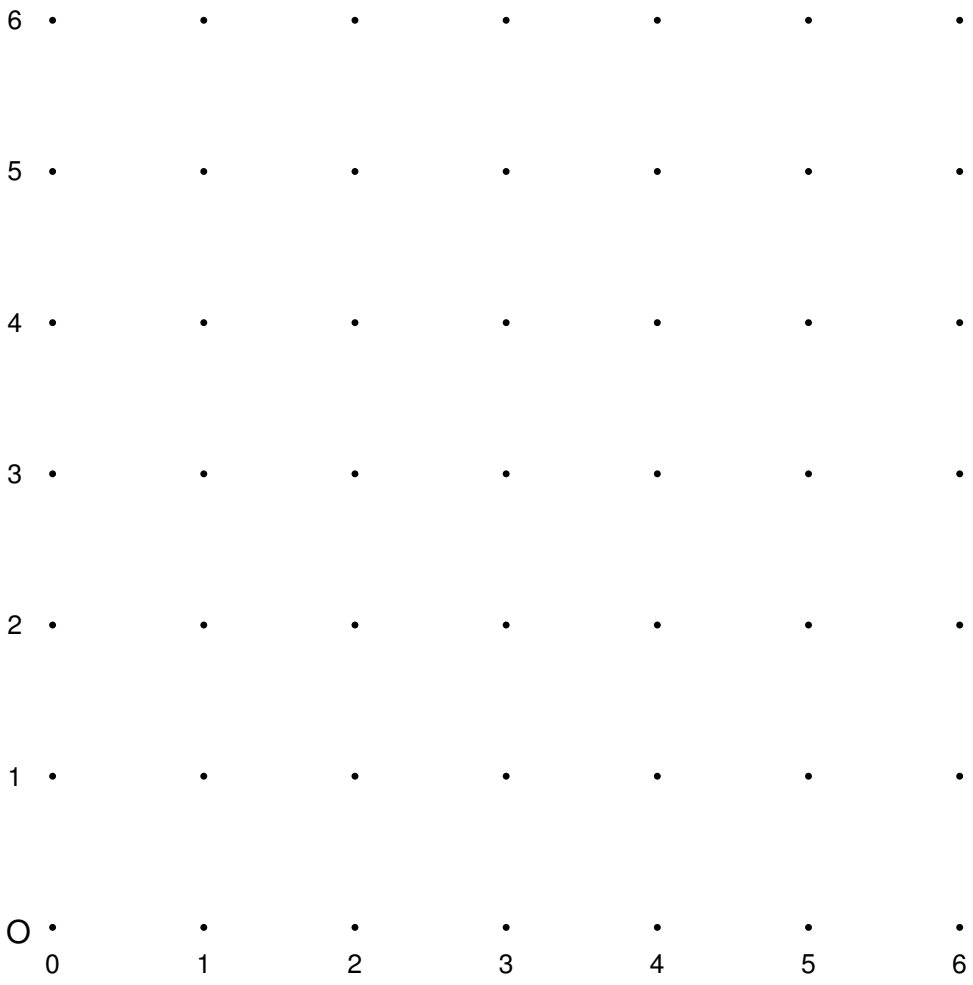
Problem 3: Predict the first dot and number of blockers for (12, 8), (15, 10), (21, 14), (25, 15) and (13, 8). Explain a rule that works for any target with whole-number coordinates.

Problem 4: A target is (a, b), with a and b positive whole numbers. Explain why a common divisor larger than 1 always produces a blocker. Does every blocker produce a common divisor?

Problem 5: List all the targets (a, b) whose two coordinates are each from 1 through 6 that have the same first visible dot as (6, 4). Repeat for (6, 3) and (6, 6). Explain why no target can belong to two different groups.



Problem 6: Let d be the greatest whole number that divides both coordinates of a target. How does d determine the first dot after O and the number of blockers? Explain why there can be no extra dots between the ones your rule finds.

Problem 7: Find an entire row of visible dots, an infinite collection of hidden dots, and a target with exactly 99 blockers. Explain each choice.
