Move a pawn on the roads. Keep each journey as ordered step tiles; an adult may record. Remove only two adjacent steps along the same road in opposite directions. Replay the other steps in order. The map, start, and finish stay fixed.

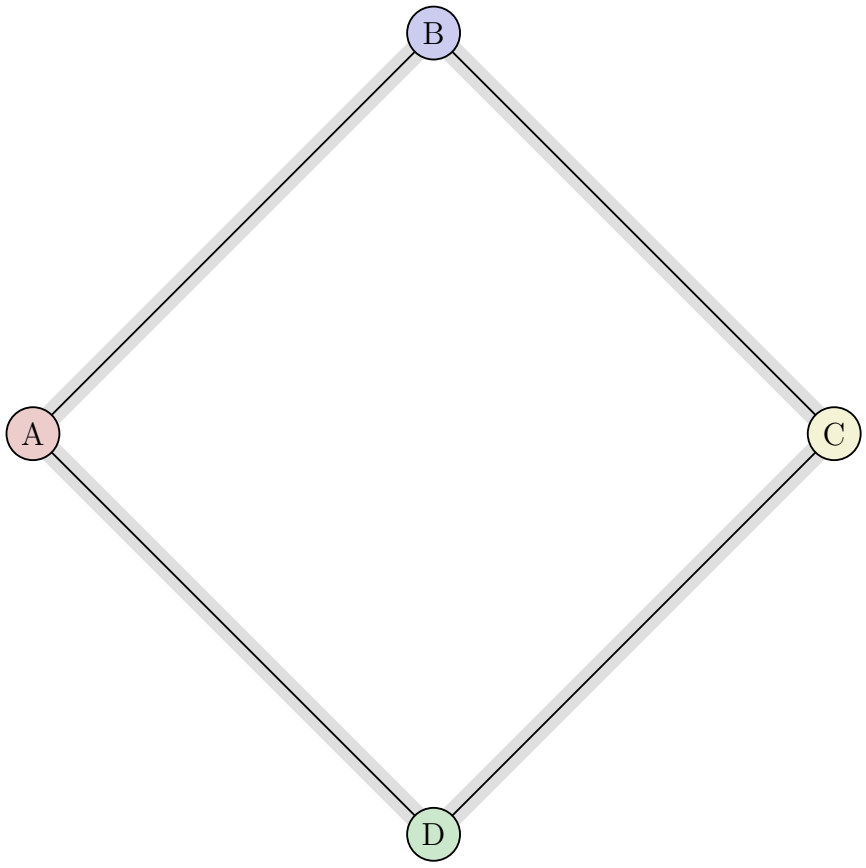

No steps left means the pawn stays at its start.

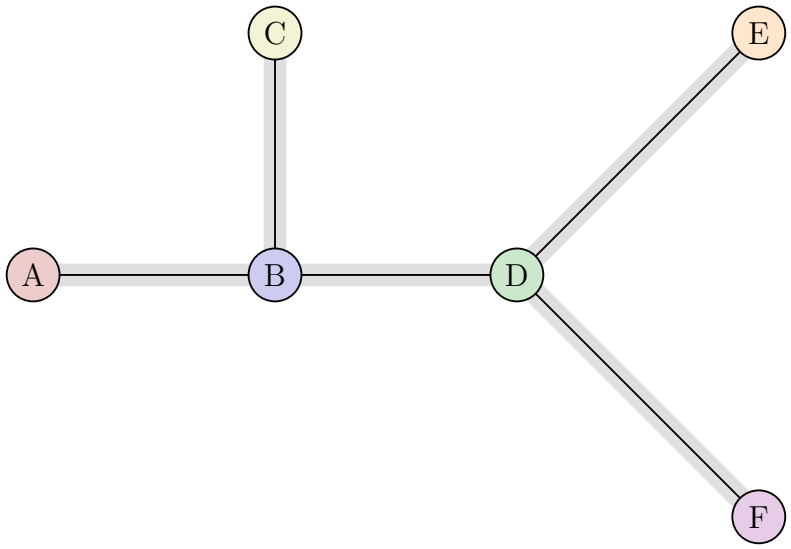

Problem 1: Make a three-step trip from A to E and four-step trips from B back to B and from A to D. Make each one as a row of step tiles, then shorten it as much as you can.

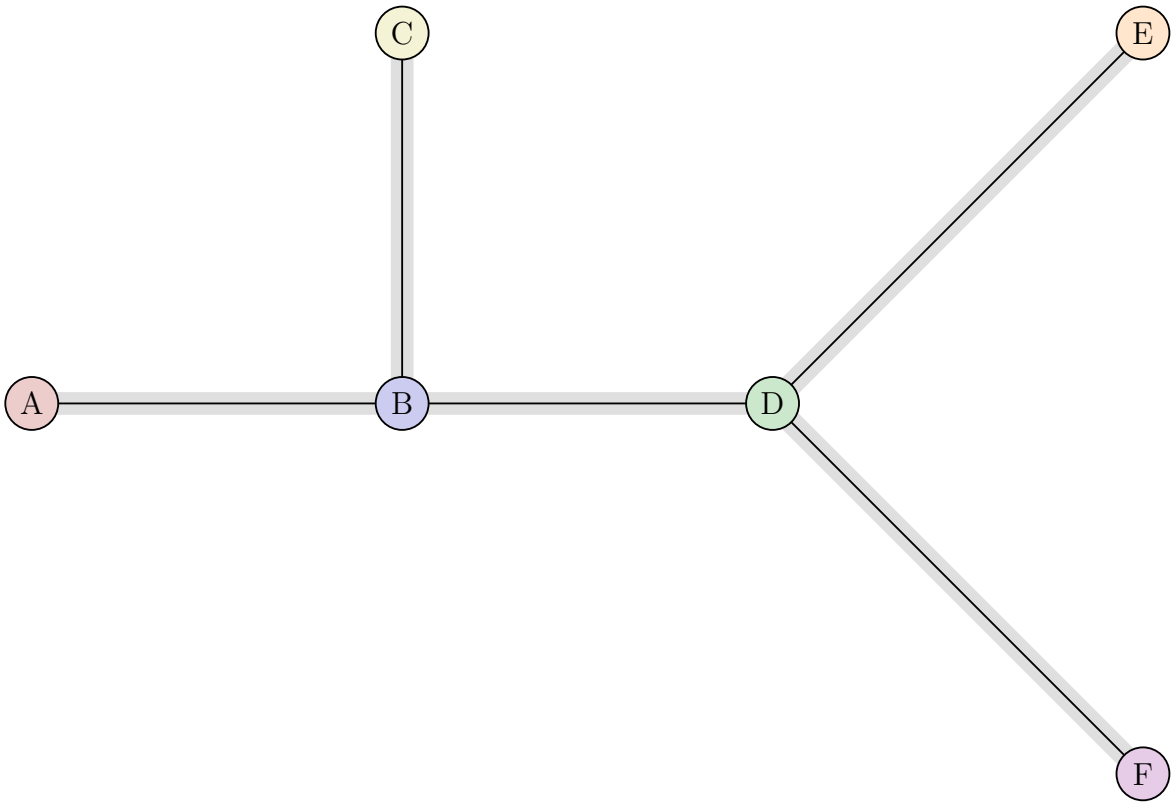

Problem 2: Make four-step trips from A back to A on this ring. Which can you shorten to staying at A, and which keep some steps?

Problem 3: Make a seven-step trip from A to E and a seven-step trip from C to F. Replay each one, removing immediate out-and-back steps until none remain.

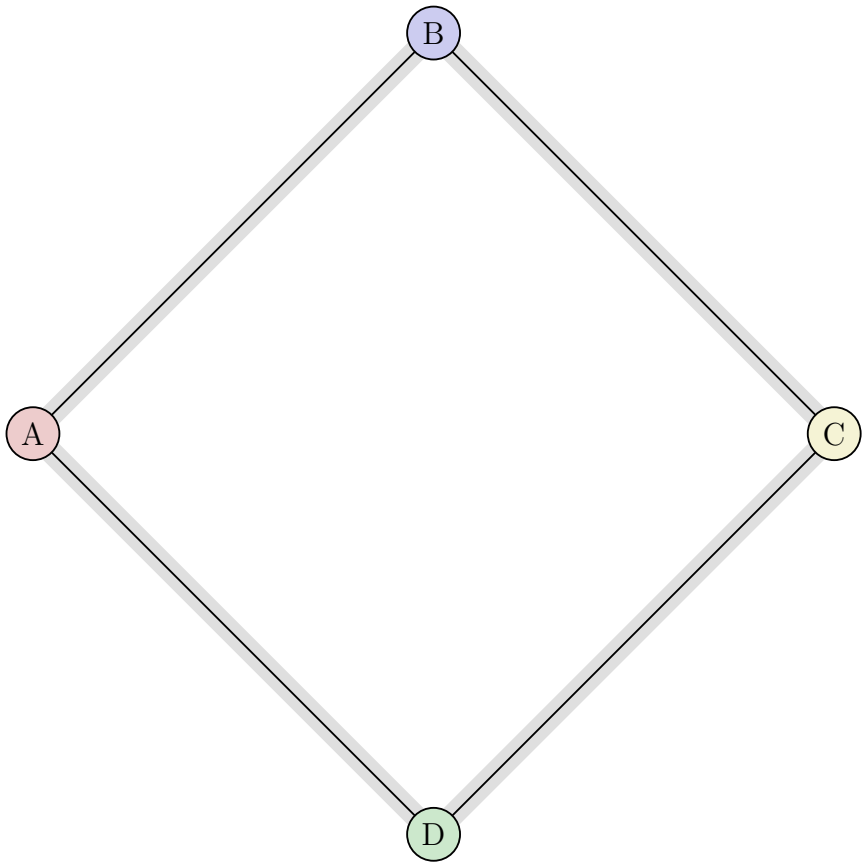

Problem 4: Make trips from A back to A using 4, 6, 8, and 12 road steps. Which can you shorten to staying at A?

Problem 5: Make a trip from C to F that uses every road. Can any such trip keep an extra road step after all immediate reversals are removed?

Problem 6: Make every different trip from A back to A that can remain after shortening an eight-step trip on this ring. Replay each result with your pawn.

Problem 7: Make every different trip from A to C that can remain after shortening a six-step trip. Can two of your remaining trips use the same four roads?
