Move one counter at a time to a neighboring bin. Each crossing costs 1. Bins hold any number of counters, and counters may pass through occupied bins. Any counter may fill any target place. Only start counters move; the target picture stays fixed. Write each move as you make it.

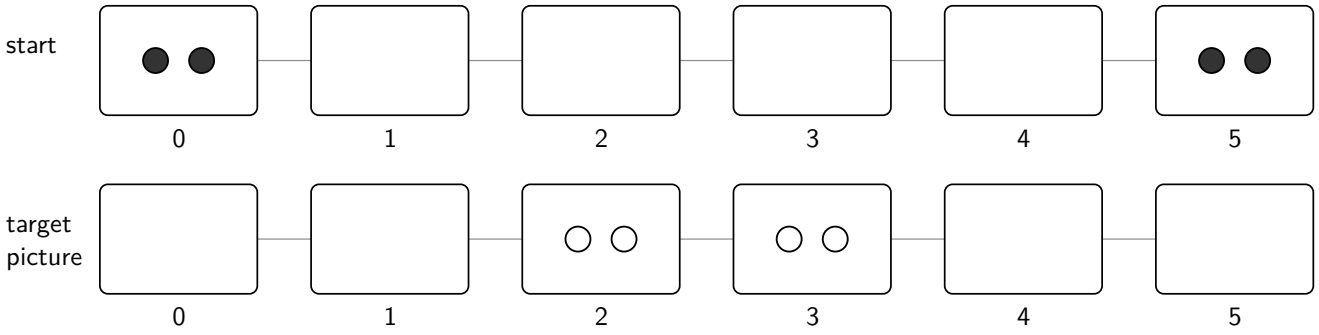

Problem 1: Make each start match its target using the least work you can.

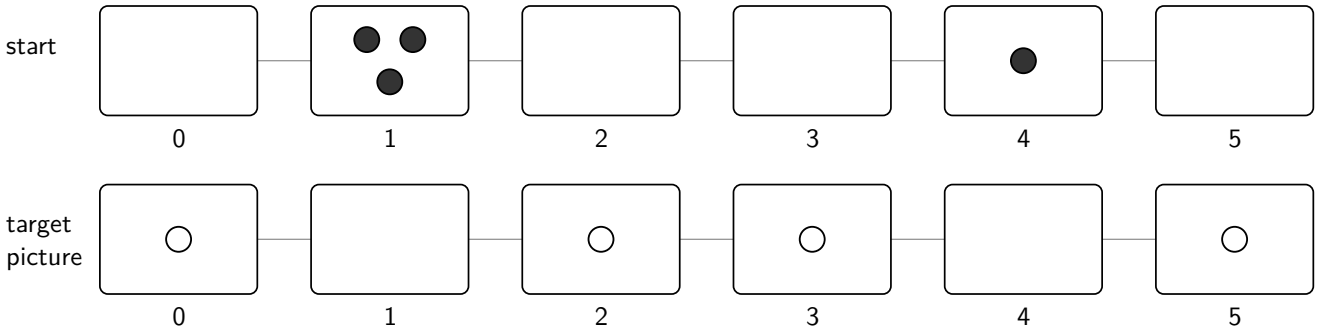

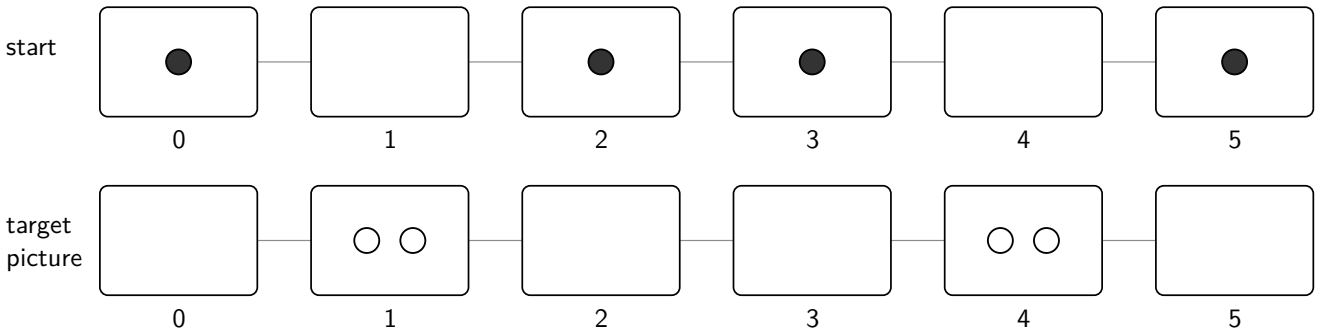

Problem 2: Find the least work for each pair. Explain why no plan can use less.

work: _____

work: _____

work: _____

Problem 3: A delivery carries one counter straight to an unfilled target place. Once delivered, that counter stays there. A rule says to make the shortest remaining delivery each time. Test this rule on both pairs. Does it always give the least work? Can tied choices change the result?
