One turn: move every cube down its own arrow, then slide the whole bottom row straight up into the top row. When you draw a machine, give every top slot one arrow going out and every bottom slot one arrow coming in. A cube is home when it is back under its own picture.

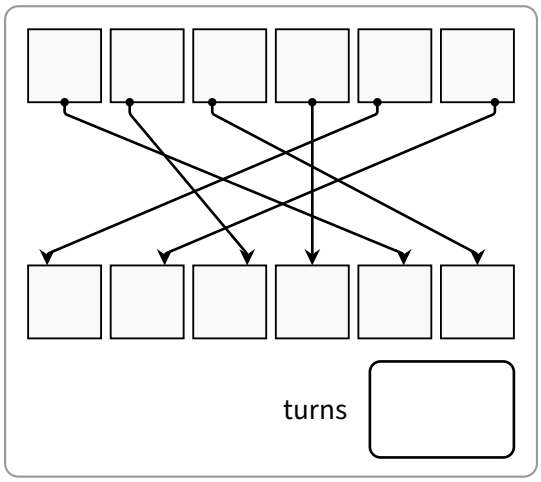

Problem 1: Put each cube under its picture and run each machine. For each cube, find the first turn after which it is back home. Then find the first turn after which all the cubes are back home at the same time.

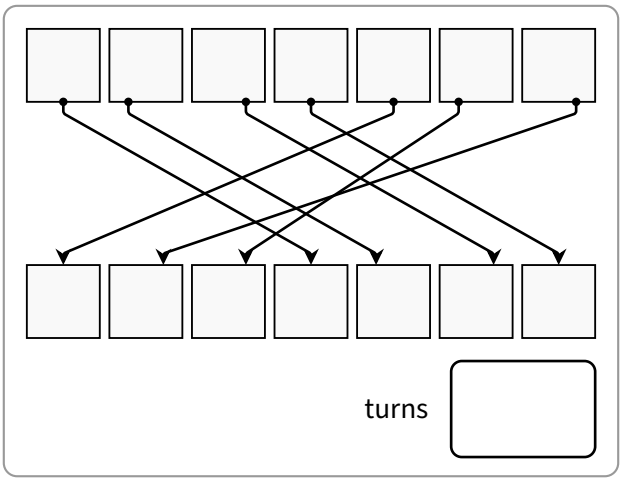

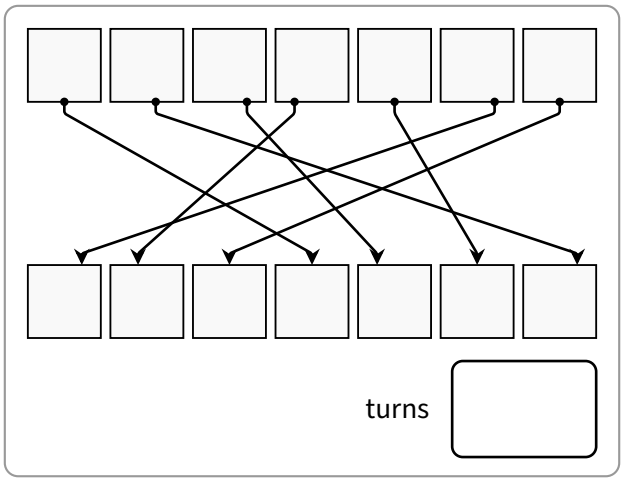

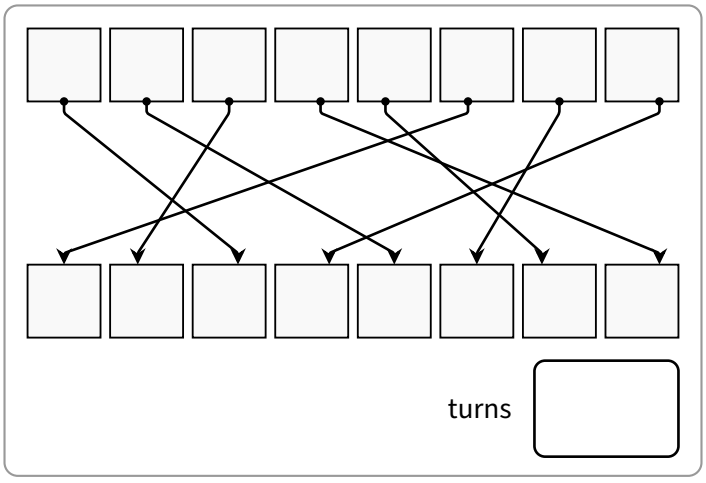

Problem 2: Without moving any cubes, find how many turns each of these machines takes to bring all the cubes home.

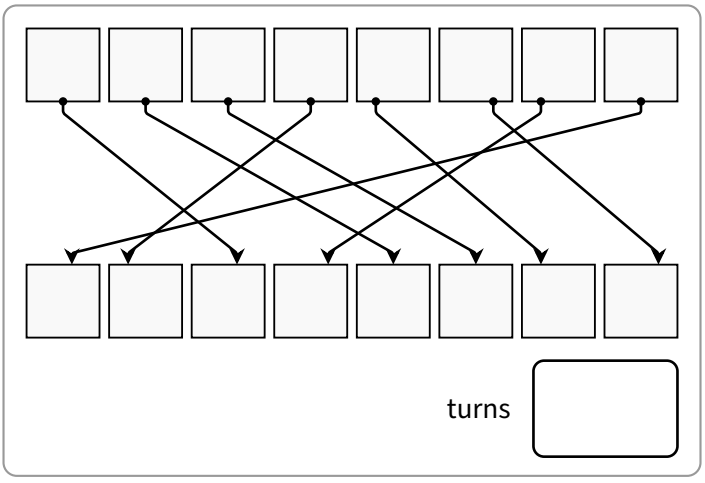

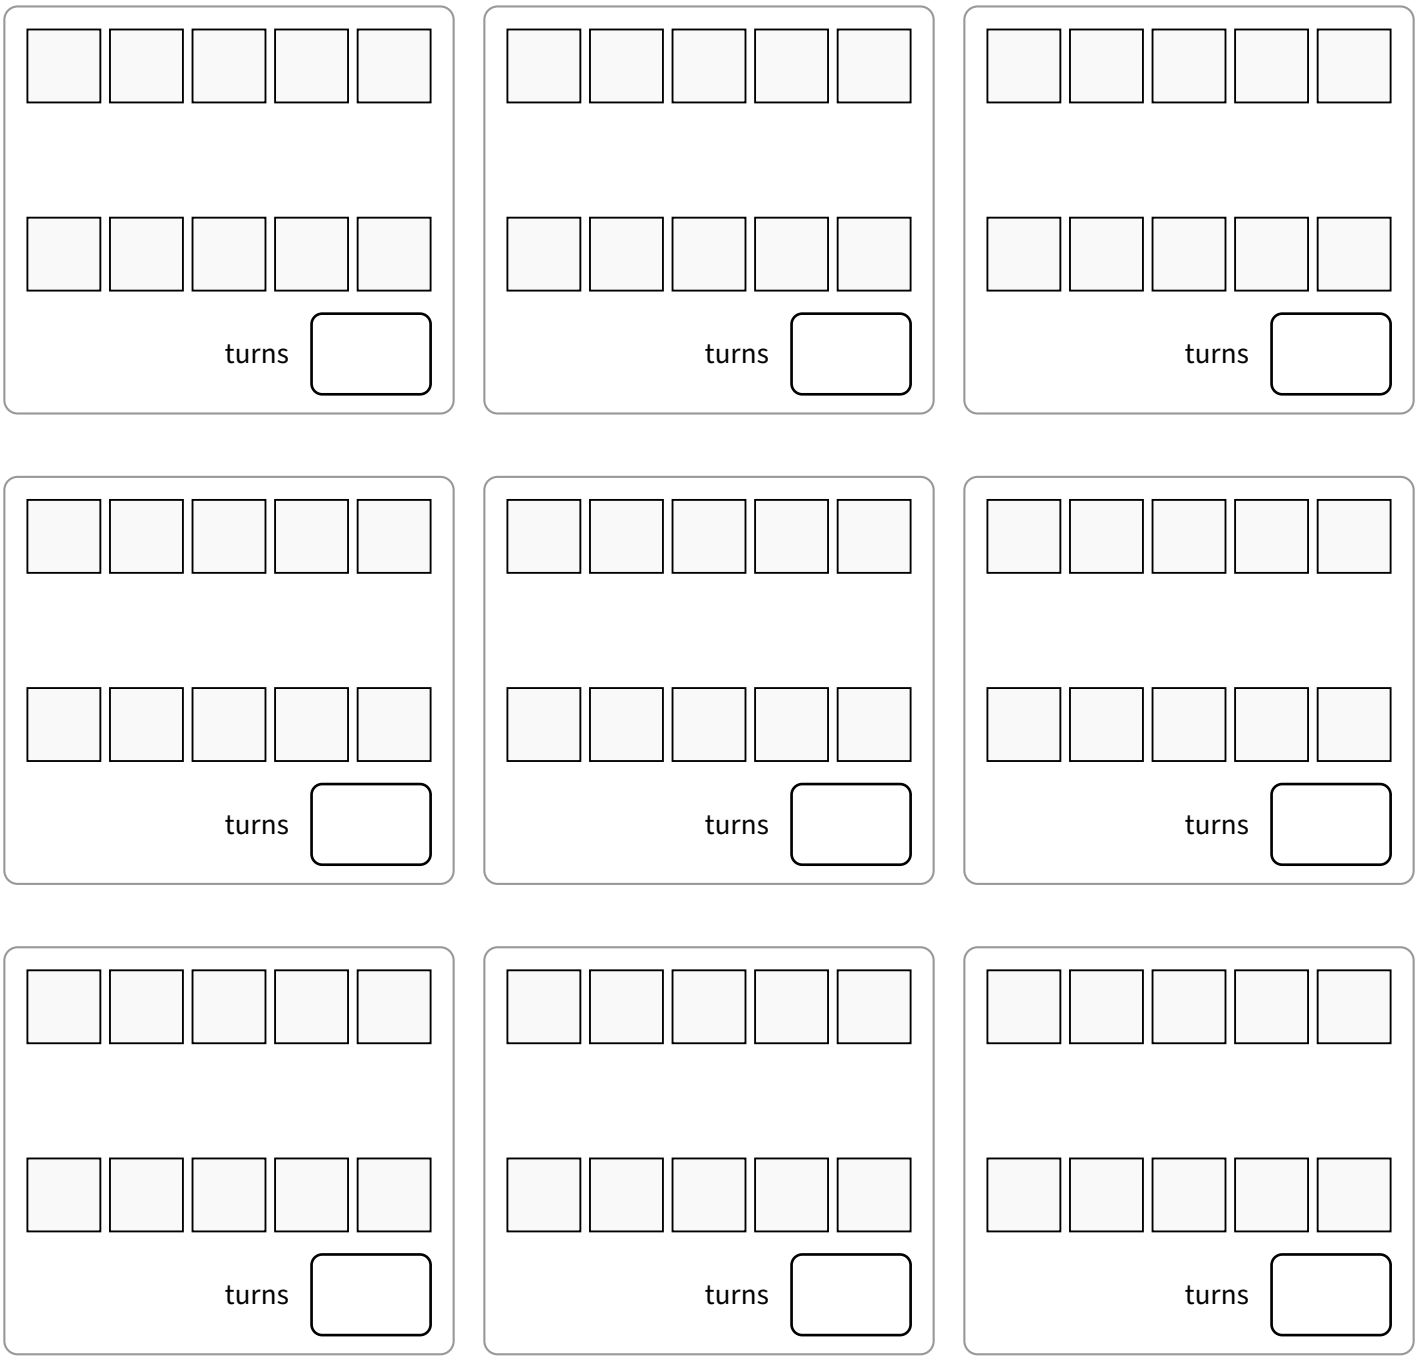

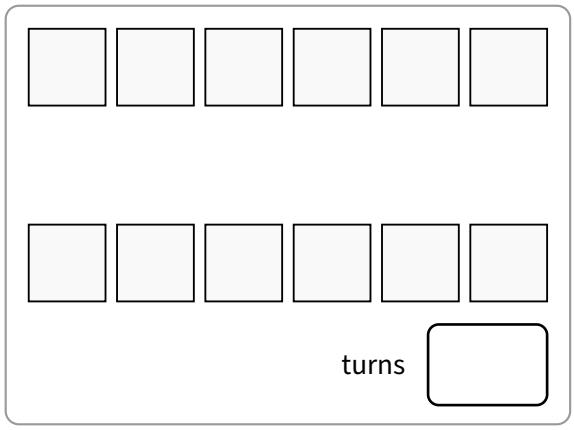

Problem 3: Which numbers of turns can a machine with 5 slots take to bring all the cubes home? Draw a machine for each number you find, and explain why no other number is possible.

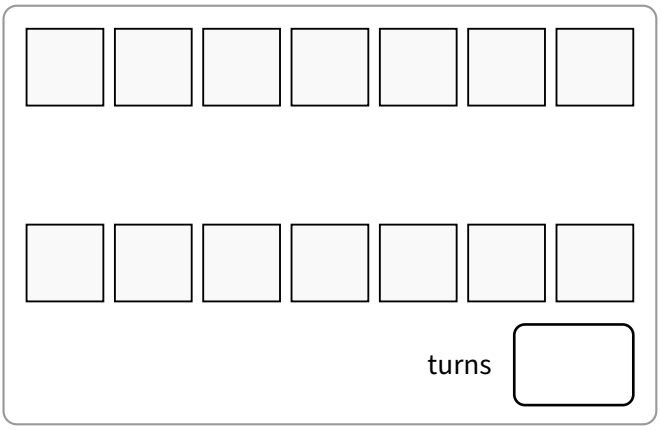

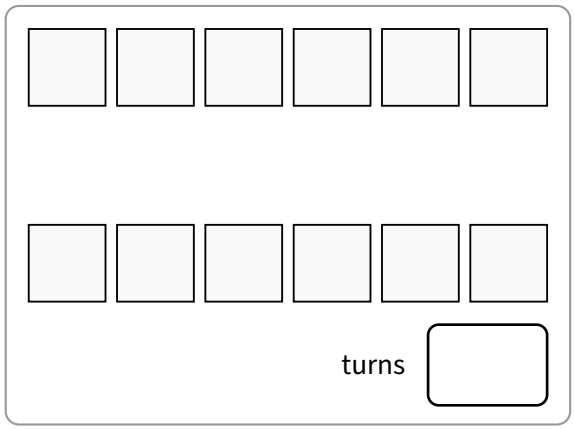

Problem 4: Find a machine with 6 slots that takes as many turns as possible to bring all the cubes home. Do the same for 7 slots. For each, explain why no machine with that many slots takes more turns.

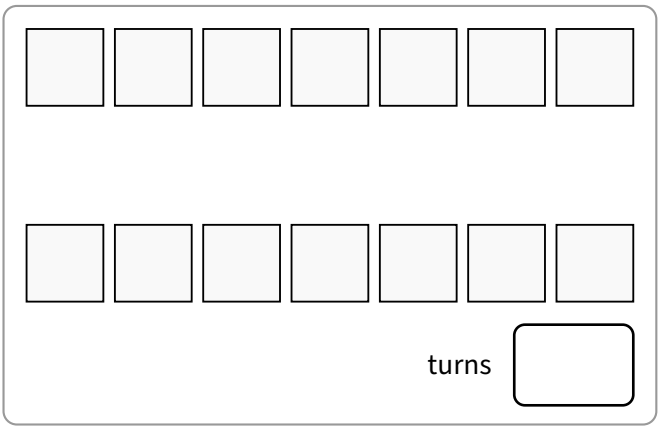

6 slots

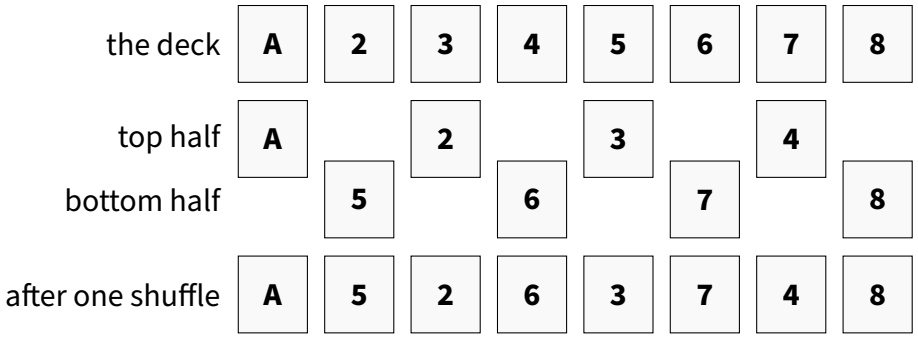

7 slots

Problem 5: A perfect shuffle splits a deck into a top half and a bottom half of the same size, then puts the halves together one card from each half at a time, keeping the top card on top. Do the shuffles with the cards laid out in a row, top card on the left.

How many perfect shuffles bring these eight cards back to their starting order? Find the number for 4, 6, 10 and 12 cards too, using the cards from A upward in one suit. Then draw the perfect shuffle of 8 cards as a machine.

cards	4	6	8	10	12
