Put your eye down at the table about a foot from one end of a row of towers and look along the row. You see a tower when it is taller than every tower in front of it.

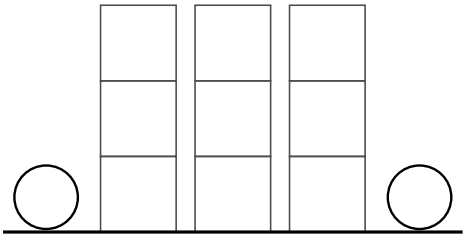

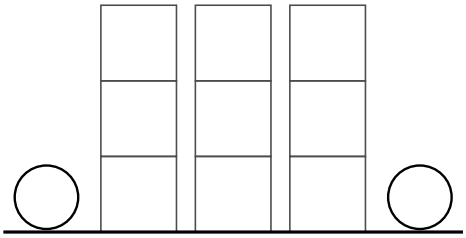

Problem 1: Make towers of 1, 2, and 3 cubes. Build each row in the picture, and write in each circle how many towers you see from that end.

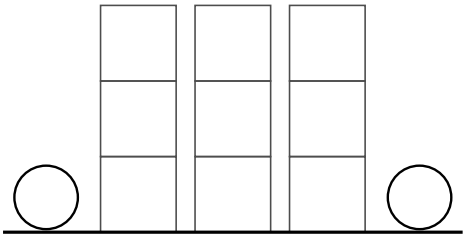

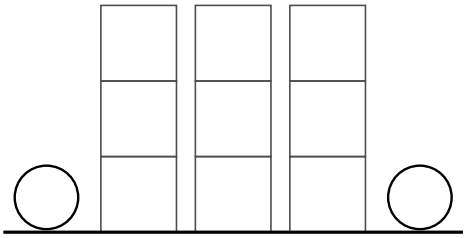

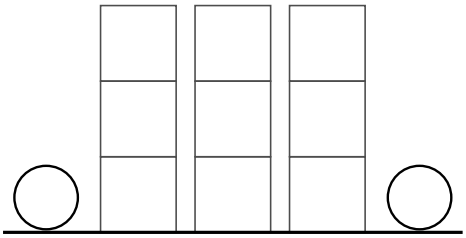

Problem 2: Find every different way to stand your three towers in a row. Draw each way, and write how many towers you see from each end.

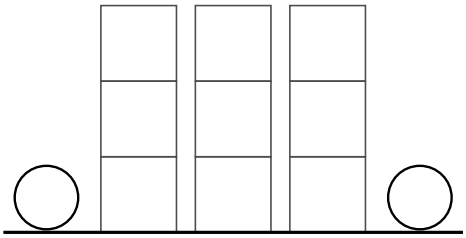

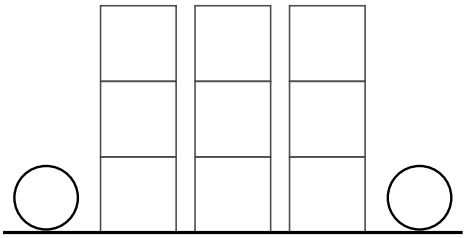

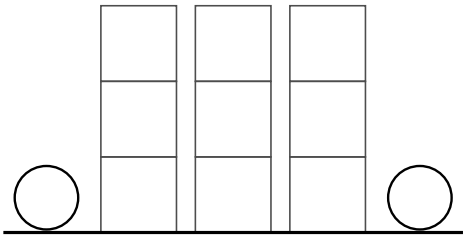

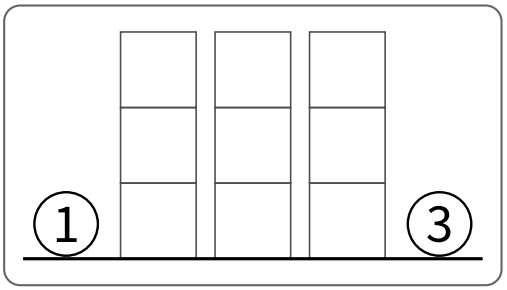

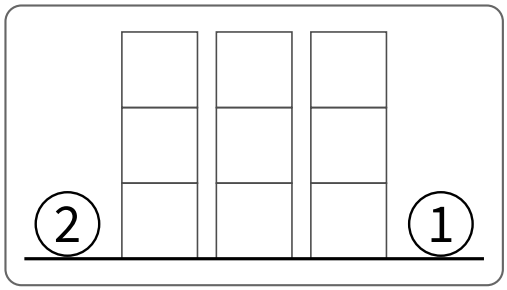

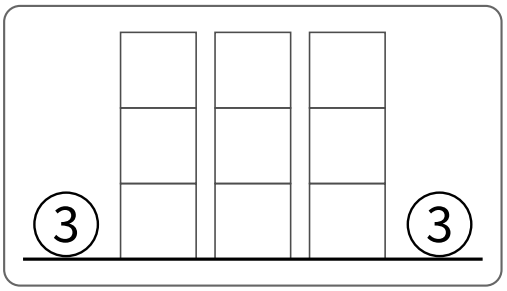

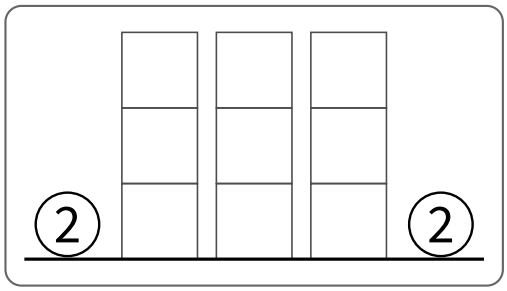

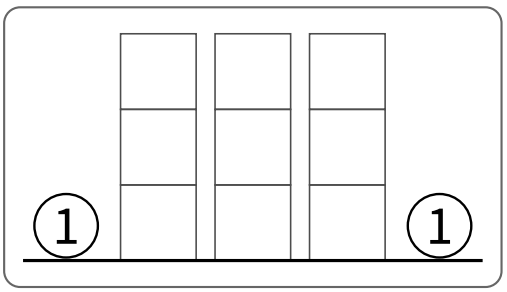

Problem 3: Build a row of your three towers that shows the two numbers on each card, and draw it. If no row can, put an X on the card and tell why.

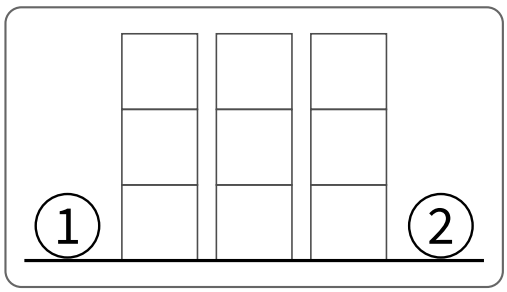

Problem 4: One partner hides a row of three towers behind a folder and says how many towers you can see from each end. The other builds a row that shows those numbers and draws it, and then you swap.
