Fill the whole polygon with triangles, using straight lines between printed corners. Lines inside a polygon may meet at corners but may not cross. Keep the corner labels fixed, even if you turn the page. Use tracing paper to change printed lines.

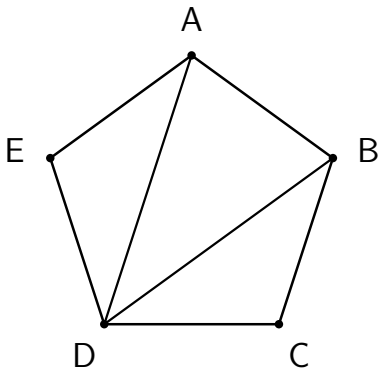

**Problem 4:** A change of one inside line that keeps the polygon filled with triangles is called a flip. Join two drawings when one flip changes one into the other. Include every possible join.

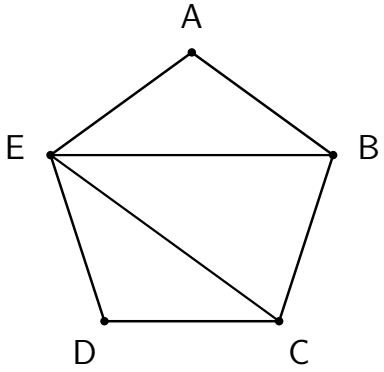

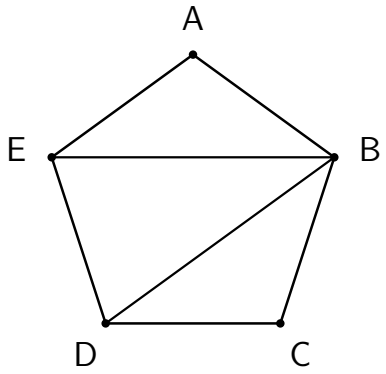

Example: erase AC, draw BD. The join connects whole fillings; it is not an inside line.

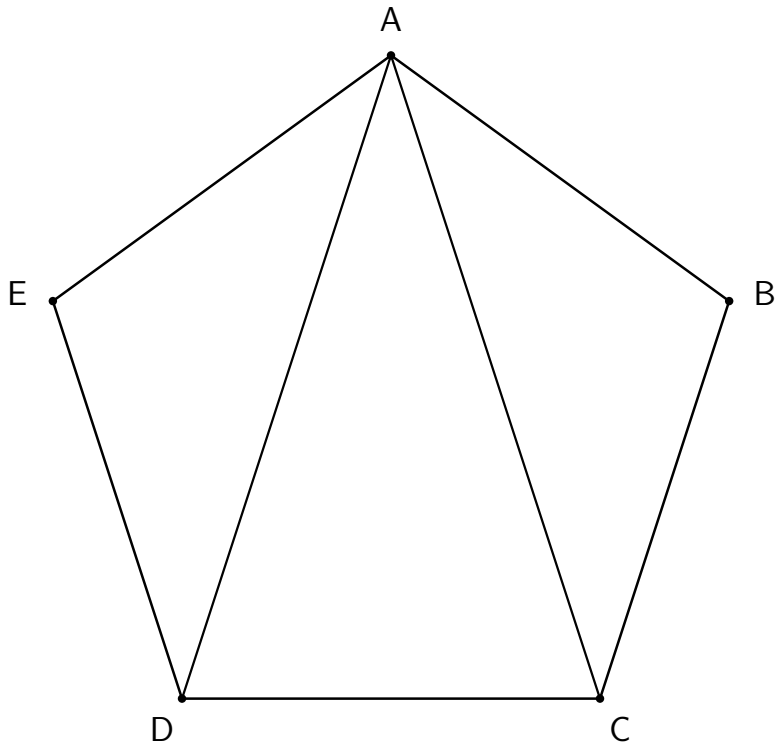

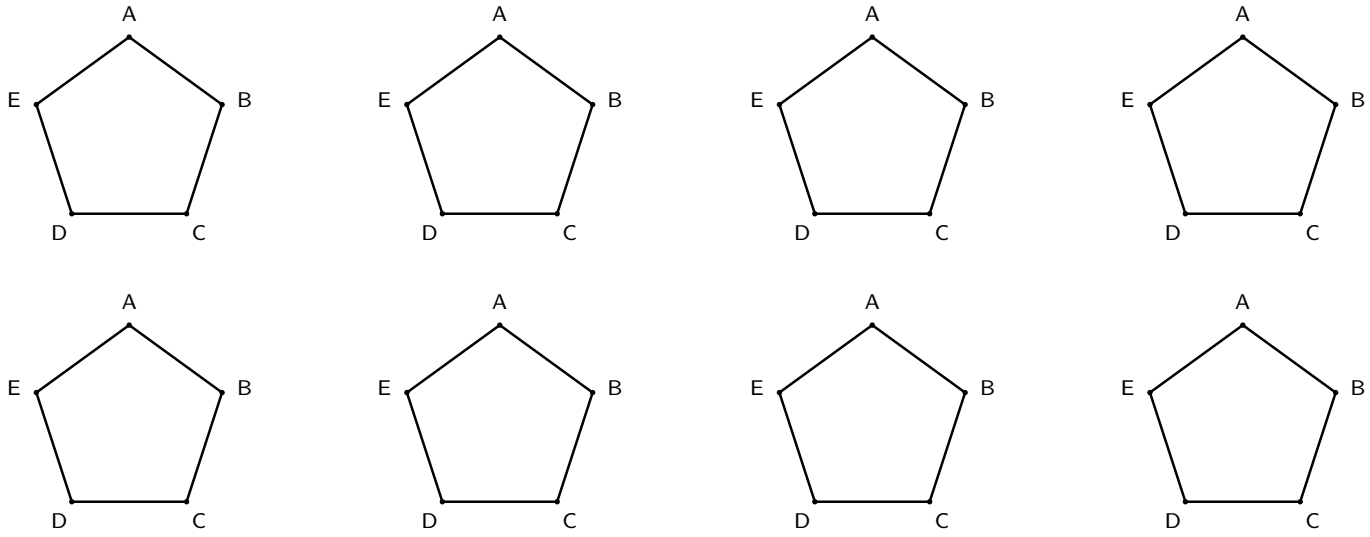

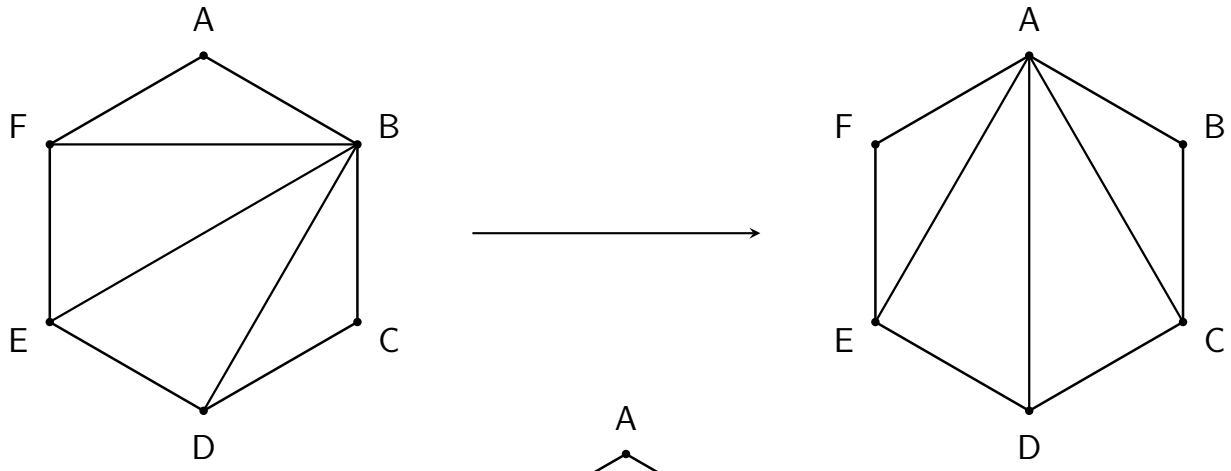

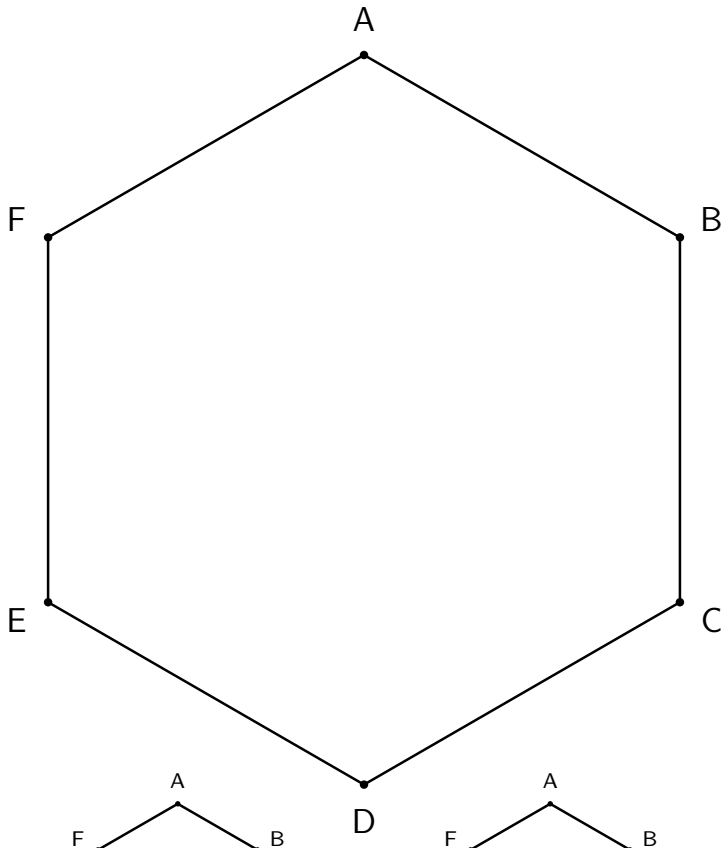

**Problem 5:** Start with this filling and return to it after an odd number of flips. Show every filling along your route.

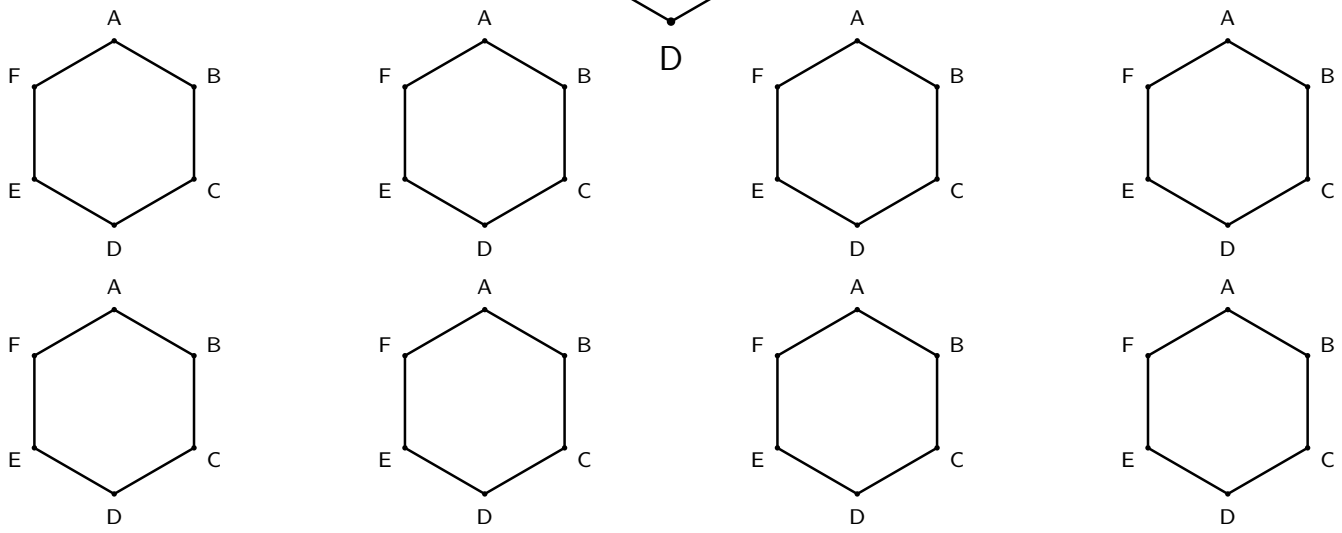

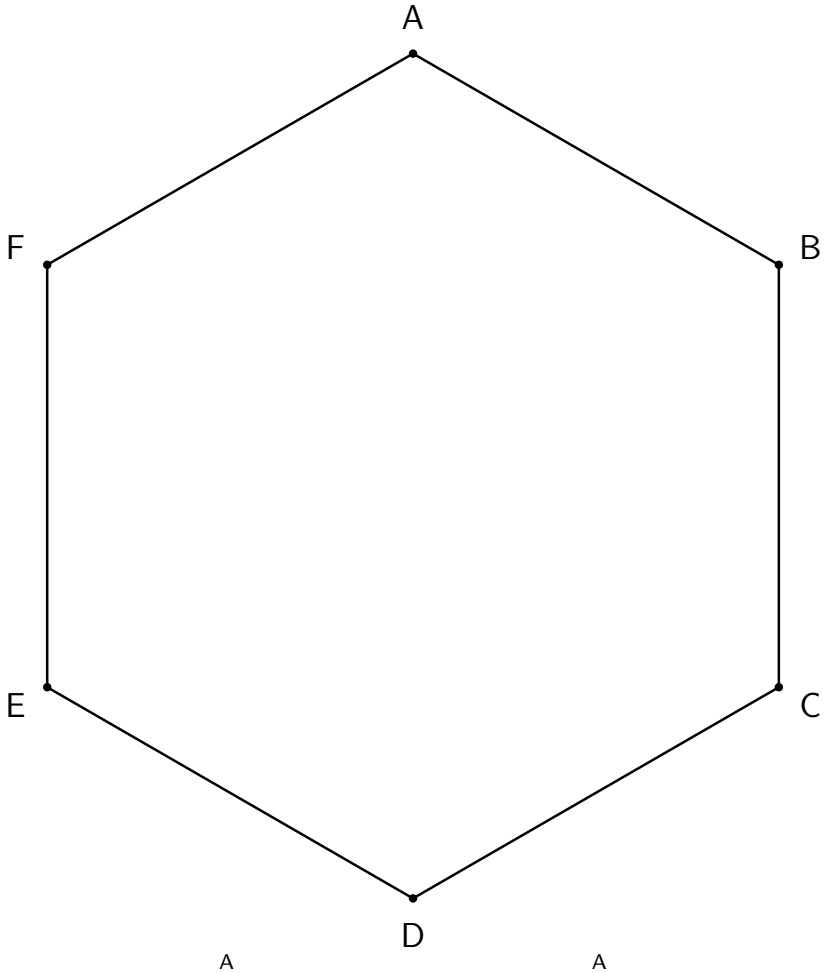

**Problem 6:** Change the first filling into the second using as few flips as you can. Find another route with a different number of flips, without visiting any filling twice.

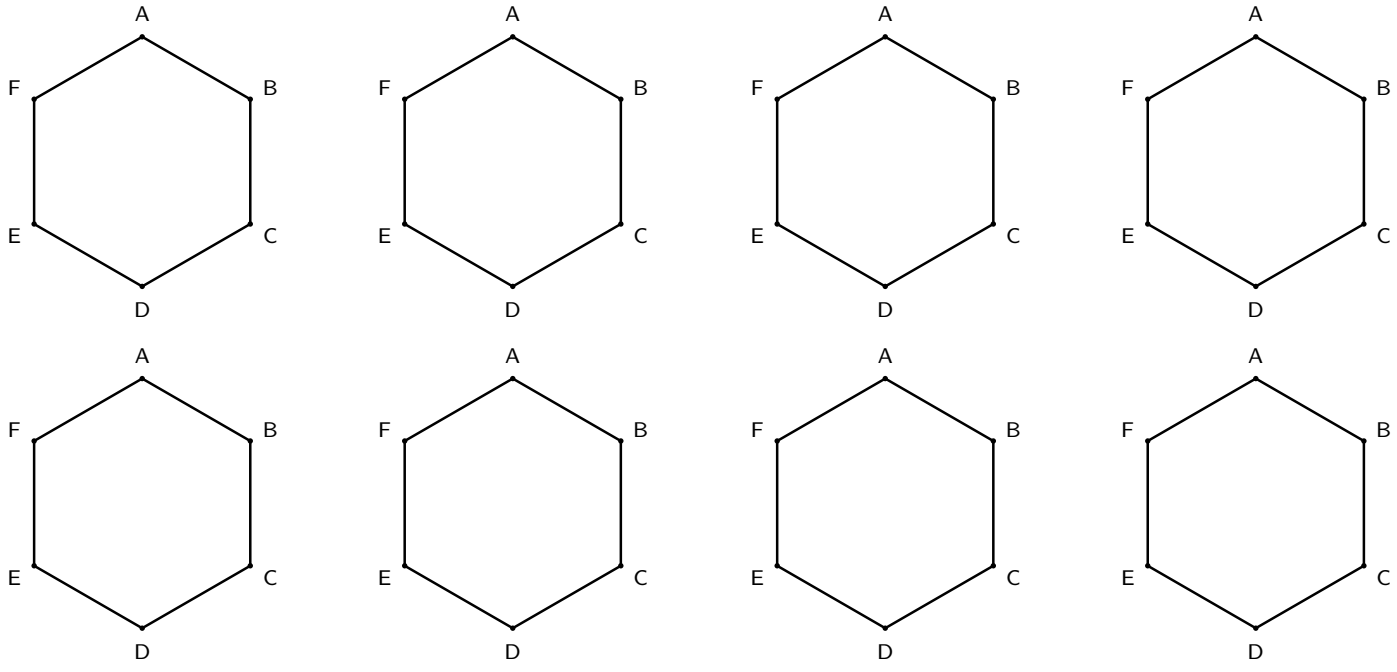

**Problem 7:** Find every filling of this six-corner polygon. Organize your drawings so you can tell whether any are missing or repeated.

**Problem 7 (continued):** Extra hexagons for your collection. Use these to continue Problem 7 on the previous page.
